

# CTEs Clause

---

The **CTE (Common Table Expression)** clause in SQL is a temporary result set that you can reference within a SELECT, INSERT, UPDATE, or DELETE statement. It makes complex queries **easier to write and read**, especially for recursive or multi-step logic.

```
WITH cte_name AS (  
    SELECT ...  
)  
SELECT * FROM cte_name;
```

# CTEs Clause

---

CTE for filtering high salary employees

```
WITH high_paid_emps AS (  
  SELECT * FROM employees  
  WHERE salary > 55000  
)  
SELECT name, dept, salary  
FROM high_paid_emps;
```

# CTEs Clause

---

## CTE with Window Function

```
WITH ranked_emps AS ( SELECT *, RANK() OVER (PARTITION BY dept ORDER BY salary DESC) AS dept_rank FROM employees ) SELECT *  
FROM ranked_emps WHERE dept_rank = 1;
```

## CTE with Joins

sql

```
WITH hr_emps AS ( SELECT * FROM employees WHERE dept = 'HR' ), sales_emps AS ( SELECT * FROM employees WHERE dept = 'Sales' )  
SELECT h.name AS hr_name, s.name AS sales_name FROM hr_emps h JOIN sales_emps s ON h.salary = s.salary;
```

# CTEs Clause

---

## Benefits of CTE

Advantage	Description
Readability	Breaks complex queries into parts
Reusability	Reuse the result of a subquery
Recursion support	Only way to write recursive queries in SQL
Optimization-friendly	CTEs are often optimized by the engine

# Views

---

A view is a database object that is a logical representation of a table. It is delivered from a table but has no storage of its own and often may be used in the same manner as a table.

A view takes the output of the query and treats it as a table, therefore a view can be thought of as a stored query or a virtual table.

## **TYPES:**

- ☐ Simple view
- ☐ Complex view
- ☐ Simple view can be created from one table where as complex view can be created from
- ☐ multiple tables.

# Views

---

SQL> Create view dept\_v as select deptno, sum(sal) t\_sal from emp group by deptno;

SQL> Create view stud as select rownum no, name, marks from student;

SQL> Create view student as select \*from student1 union select \*from student2;

SQL> Create view stud as select distinct no,name from student;

# Materialized Views

---

## Use Case

 **Performance Improvement**

 **Query Caching**

 **Data Warehousing**

 **Replication**

## Description

Speeds up complex joins, aggregations, and queries on large datasets.

Stores the query result so it doesn't need to be re-computed each time.

Common in OLAP and reporting environments.

Useful in distributed systems for replicating data across databases.

# Materialized Views

---

```
CREATE MATERIALIZED VIEW mv_sales_summary  
BUILD IMMEDIATE  
REFRESH FAST ON COMMIT  
AS  
SELECT region, SUM(sales) AS total_sales  
FROM sales  
GROUP BY region;
```

# INDEXES

---

Index is typically a listing of keywords accompanied by the location of information on a subject. We can create indexes explicitly to speed up SQL statement execution on a table. The index points directly to the location of the rows containing the value.

## WHY INDEXES?

Indexes are most useful on larger tables, on columns that are likely to appear in where clauses as simple equality.

# INDEXES

---

## ❑ TYPES

❑ Unique index

❑ Non-unique index

❑ Btree index

❑ Bitmap index

❑ Composite index

❑ Reverse key index

❑ Function-based index

❑ Descending index

❑ Domain index

❑ Object index

❑ Cluster index

❑ Text index

# INDEXES

---

## UNIQUE INDEX

Unique indexes guarantee that no two rows of a table have duplicate values in the columns that define the index. Unique index is automatically created when primary key or unique constraint is created.

Ex:

```
SQL> create unique index stud_ind on student(sno);
```

## NON-UNIQUE INDEX

Non-Unique indexes do not impose the above restriction on the column values.

Ex:

```
SQL> create index stud_ind on student(sno);
```

# INDEXES

---

## **BTREE INDEX or ASCENDING INDEX**

The default type of index used in an oracle database is the btree index. A btree index is designed to provide both rapid access to individual rows and quick access to groups of rows within a range. The btree index does this by performing a succession of value comparisons. Each comparison eliminates many of the rows.

Ex:

```
SQL> create index stud_ind on student(sno);
```

# INDEXES

---

## BTREE INDEX or ASCENDING INDEX

# INDEXES

---

## **BITMAP INDEX**

This can be used for low cardinality columns: that is columns in which the number of distinct values is small when compared to the number of the rows in the table.

Ex:

```
SQL> create bitmap index stud_ind on student(sex);
```

# INDEXES

## BITMAP INDEX

# INDEXES

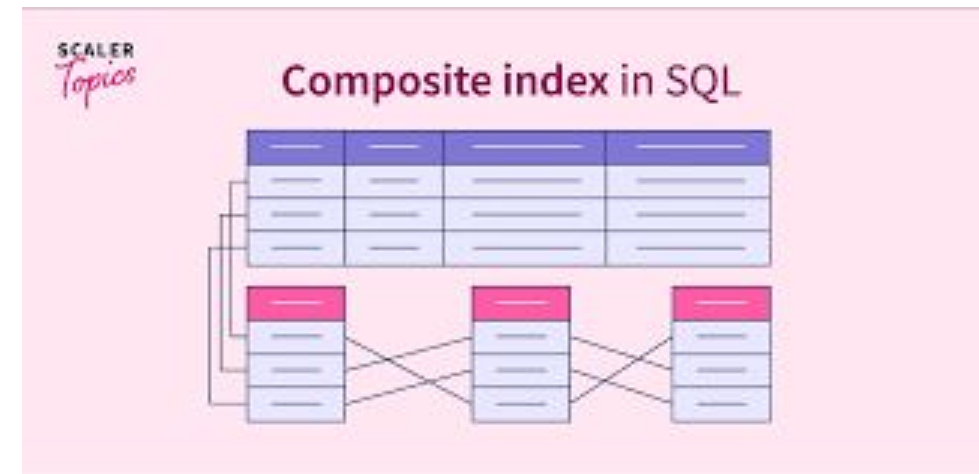

---

## COMPOSITE INDEX

A composite index also called a concatenated index is an index created on multiple columns of a table. Columns in a composite index can appear in any order and need not be adjacent columns of the table.

Ex:

```
SQL> create bitmap index stud_ind on student(sno, sname);
```

# INDEXES

---

## REVERSE KEY INDEX

A reverse key index when compared to standard index, reverses each byte of the column being indexed while keeping the column order. When the column is indexed in reverse mode then the column values will be stored in an index in different blocks as the starting value differs. Such an arrangement can help avoid performance degradations in indexes where modifications to the index are concentrated on a small set of blocks.

Ex:

```
SQL> create index stud_ind on student(sno, reverse);
```

We can rebuild a reverse key index into normal index using the noreverse keyword.

# INDEXES

## REVERSE KEY INDEX

# INDEXES

---

## FUNCTION BASED INDEX

This will use result of the function as key instead of using column as the value for the key.

view

Ex:

```
SQL> create index stud_ind on student(upper(sname));
```

## FUNCTION BASED INDEX

This will use result of the function as key instead of using column as the value for the key.

view

Ex:

```
SQL> create index stud_ind on student(upper(sname));
```

# INDEXES ----details

---

## TEXT INDEX

Querying text is different from querying data because words have shades of meaning, relationships to other words, and opposites. You may want to search for words that are near each other, or words that are related to others. These queries would be extremely difficult if all you had available was the standard relational operators. By extending SQL to include text indexes, oracle text permits you to ask very complex questions about the text.

# INDEXES ----details

---

## HOW TO CREATE TEXT INDEX?

You can create a text index via a special version of the create index command. For context index, specify the ctxsys.context index type and for ctxcat index, specify the ctxsys.ctxcat index type.

Ex:

Suppose you have a table called BOOKS with the following columns

Title, Author, Info.

```
SQL> create index book_index on books(info) indextype is ctxsys.context;
```

```
SQL> create index book_index on books(info) indextype is ctxsys.ctxcat;
```

# INDEXES

---

## MONITORING USE OF INDEXES

Once you turned on the monitoring the use of indexes, then we can check whether the table is hitting the index or not.

To monitor the use of index use the following syntax.

Syntax:

```
alter index index_name monitoring usage;
```

# Schema Normalization in DBMS

---

**Normalization** is the process of organizing data in a database to eliminate **redundancy** and improve **data integrity**.

It is done by applying a series of **normal forms (NF)** — each form has rules that a table must follow.

## Benefit

- ✓ Removes redundancy
- ✓ Ensures consistency
- ✓ Saves storage
- ✓ Improves data integrity

## Description

- Avoids duplicate data
- Data is updated in one place
- Fewer repeating values
- Enforces meaningful relationships

# EXPLAIN PLAN

---

EXPLAIN PLAN shows the **steps and order** Oracle will follow to execute a SQL statement — including things

```
EXPLAIN PLAN FOR  
SELECT emp_id, name, salary, LEAD(salary) OVER (ORDER BY emp_id) AS next_salary FROM employees;  
  
SELECT * FROM TABLE(DBMS_XPLAN.DISPLAY);
```

# TOP 5 Rows Fetch

---

```
SELECT *  
FROM employees  
FETCH FIRST 5 ROWS ONLY;
```
